#### Abstract

In this paper, we study Riemannian optimization methods for the problem of nonnegative matrix completion that is to recover a nonnegative low rank matrix from its partial observed entries. With the underlying matrix incohence conditions, we show that when the number $m$ of observed entries are sampled independently and uniformly without replacement, the inexact Riemannian gradient descent method can recover the underlying $n_{1}$-by- $n_{2}$ nonnegative matrix of rank $r$ provided that $m$ is of $\mathcal{O}\left(r^{2} s \log ^{2} s\right)$, where $s=\max \left\{n_{1}, n_{2}\right\}$. Numerical examples are given to illustrate that the nonnegativity property would be useful in the matrix recovery. In particular, we demonstrate the number of samples required to recover the underlying low rank matrix with using the nonnegativity property is smaller than that without using the property.

## 1 Introduction

Matrix completion, the problem of filling the missing elements by partially observed matrices became popular after the Netflix prize competition which was held in 2006. In order to avoiding being an underdetermined and intractable problem, low rank is often a necessary hypothesis to restrict the degree of freedoms of the missing entries. The matrix completion problem can be formulated as the following optimization problem:

$$
\begin{align*}
& \operatorname{minimize} \operatorname{rank}(X) \\
& \text { subject to } P_{\Omega}(X)=P_{\Omega}(A), \tag{1.1}
\end{align*}
$$

where $X \in \mathbb{R}^{n_{1} \times n_{2}}$ is the decision variable, the set $\Omega$ of locations corresponding to the observed entries $\left((i, j) \in \Omega\right.$ if $A_{i j}$ is observed) is a set of cardinality $m$ sampled uniformly at random, and the corresponding sampling operator $P_{\Omega}$ is defined by

$$
\left[P_{\Omega}(X)\right]_{i, j}= \begin{cases}X_{i j}, & \text { if }(i, j) \in \Omega \\ 0, & \text { otherwise }\end{cases}
$$

In general, the rank minimization problem listed in (1.1) is NP-hard and computationally intractable. Many methods were proposed to solve the matrix completion problem, see for instance $[1-4,6-14]$. In general, it can be divided into two categories: convex and non-convex optimization methods. Under the framework of convex optimization, the nuclear norm minimization problem

$$
\begin{align*}
& \text { minimize }\|X\|_{*} \\
& \text { subject to } P_{\Omega}(X)=P_{\Omega}(A), \tag{1.2}
\end{align*}
$$

is often applied to recover the unknown matrix entries, where the nuclear norm $\|X\|_{*}$ of a matrix $X$ is defined as the sum of its singular values. With some suitable assumptions (incoherence conditions), it has been shown that if the number of observed entries satisfies $m \sim \mathcal{O}\left(s r^{2} \log ^{\alpha} s\right)$ for some $\alpha \geq 0$, the underlying rank $r$ matrix can be exactly recovered with high probability, where $s=\max \left\{n_{1}, n_{2}\right\}$. Meanwhile, many computationally efficient algorithms are designed to solve model (1.2), see [15-18] and references therein. On the other hand, there are non-convex optimization methods for solving (1.1) by parameterizing in a factorization form or studying in a set of fixed rank matrices. The computational cost of most non-convex algorithms are shown to be cheaper than that of the convex methods. The major issue is how to choose suitable initial guesses in non-convex optimization methods such that they can converge to the underlying low rank solution.

Nonnegative data matrices appear in many data analysis applications. For instance, in image analysis, image pixel values are nonnegative and the associated nonnegative image data matrices can be formed for clustering and recognition, see for instance [19-30]. In text mining, the frequencies of terms in documents are nonnegative and the resulted nonnegative term-to-document data matrices can be constructed for clustering, see for example [31-34]. In bioinformatics, nonnegative gene expression values are studied and non- negative gene expression data matrices are generated for diseases and genes classification, see [35-39]. The main aim of this paper is to study the problem of nonnegative matrix completion by introducing nonnegativity requirement for $X$ in (1.1). In the literature, Xu et al. [42] proposed to solve the nonnegative matrix completion problem by using an algorithm based on the classical alternating direction augmented Lagrangian method. In [43], Xu and Yin designed a block coordinate descent method to study the nonnegative matrix completion problem. However, there is no theoretical result for the exact recovery of the underlying nonnegative low rank matrix.

In this paper, we study the Riemannian optimization methods for the problem of nonnegative matrix completion:

$$
\begin{align*}
& \operatorname{minimize} \frac{1}{2}\left\|P_{\Omega}(X)-P_{\Omega}(A)\right\|_{F}^{2} \\
& \text { subject to } \quad \operatorname{rank}(X)=r, \quad X \geq 0, \tag{1.3}
\end{align*}
$$

that is to recover a nonnegative low rank matrix from its partial observed entries. With the underlying low rank matrix incohence conditions, we show that when the number $m$ of observed entries are sampled independently and uniformly without replacement, the inexact Riemannian gradient descent method can recover the underlying $n_{1}$-by- $n_{2}$ nonnegative matrix of rank $r$ provided that $m$ is of $\mathcal{O}\left(r^{2} s \log ^{2} s\right)$, where $s=\max \left\{n_{1}, n_{2}\right\}$. Numerical examples are given to illustrate that the nonnegativity property would be useful in the matrix recovery. In particular, we demonstrate the number of samples required to recover the underlying low rank matrix with using the nonnegativity property is smaller than that without using the property.

The rest of this paper is organized as follows. In Section 2, we study the Riemannian gradient descent method for solving (1.3). In Section 3, we provide the bounds on the number of sampled entries required for nonnegative low rank matrix completion. In Section 4, numerical examples are given to show the advantages of the proposed methods. Finally, some concluding remarks are given in Section 5.

## 2 The proposed algorithm

### 2.1 Mathematical preliminaries

Denote

$$
\begin{equation*}
\mathcal{M}_{r}:=\left\{X \in \mathbb{R}^{n_{1} \times n_{2}}, \operatorname{rank}(X)=r\right\} \tag{2.1}
\end{equation*}
$$

as the set of all $n_{1} \times n_{2}$ rank $r$ matrices. It is well known that $\mathcal{M}_{r}$ forms an embedded submanifold of the set of matrices with size $n_{1} \times n_{2}$. And when the matrices in $\mathcal{M}_{r}$ be endowed with the usual trace inner product, then $\mathcal{M}_{r}$ forms a Riemannian submanifold of the embedding space $\mathbb{R}^{n_{1} \times n_{2}}$. Denote

$$
\begin{equation*}
\mathcal{M}_{n}:=\left\{X \in \mathbb{R}^{n_{1} \times n_{2}}, X_{i, j} \geq 0, i=1, \cdots, n_{1}, j=1, \cdots, n_{2}\right\} \tag{2.2}
\end{equation*}
$$

as the $n_{1} \times n_{2}$ nonnegativity matrices set. The projection onto the fixed rank matrix set $\mathcal{M}_{r}$ is derived by the Eckart-Young-Mirsky theorem [40] which can be expressed as

$$
\begin{equation*}
\pi_{r}(X)=\sum_{i=1}^{r} \sigma_{i}(X) u_{i}(X) v_{i}^{T}(X) \tag{2.3}
\end{equation*}
$$

where $\sigma_{i}(X), i=1, \cdots, r$ are first $r$ singular values of $X$, and $u_{i}(X), v_{i}(X)$ are first $r$ columns of the unitary matrices of $U(X)$ and $V(X)$. The projection onto the nonnegative matrix set $\mathcal{M}_{n}$ is expressed as

$$
\pi_{+}(X)= \begin{cases}X_{i j}, & \text { if } \quad X_{i j} \geq 0  \tag{2.4}\\ 0, & \text { if } \quad X_{i j}<0\end{cases}
$$

Let $X \in \mathbb{R}^{n_{1} \times n_{2}}$ be an arbitrary matrix in the manifold $\mathcal{M}_{r}$, and $X=$ $U(X) \Sigma(X) V(X)^{T}$ be a skinny SVD decomposition of $X$. It follows from [41, Proposition 2.1] that the tangent space of $\mathcal{M}_{r}$ at $X$ can be expressed as

$$
\begin{equation*}
T_{\mathcal{M}_{r}}(X)=\left\{U(X) W^{T}+Z V(X)^{T} \mid W \in \mathbb{R}^{n_{2} \times r}, Z \in \mathbb{R}^{n_{1} \times r} \text { are arbitrary }\right\} . \tag{2.5}
\end{equation*}
$$

For a given matrix $Y$, the projection of $Y$ onto the subspace $T_{\mathcal{M}_{r}}(X)$ can be written as

$$
\begin{equation*}
P_{T_{\mathcal{M}_{r}}(X)}(Y)=U(X) U(X)^{T} Y+Y V(X) V(X)^{T}-U(X) U(X)^{T} Y V(X) V(X)^{T} . \tag{2.6}
\end{equation*}
$$

### 2.2 The inexact Riemannian gradient descent method

In this subsection, an Inexact Riemannian gradient descent method (IRGD) is studied to solve the nonnegative low rank matrix completion problem. Different from

Figure 1: Inexact Riemannian gradient decent method using tangent spaces.
the Riemannian gradient descent method [17], there is an additional step in the inexact version that projects the iterate onto the nonnegative matrix manifold $\mathcal{M}_{n}$, see Fig. 1.

In the algorithm, $X_{0}=\pi_{r}\left(P_{\Omega}(A)\right)$ is a SVD (singular value decomposition) truncation of the observed matrix $P_{\Omega}(A) . T_{l}$ refers to the tangent space of $\mathcal{M}_{r}$ at $X_{l}$ defined as in (2.5), and $P_{T_{l}}\left(G_{l}\right)$ refers to the projection of $G_{l}$ onto $T_{l}$ defined as in (2.6). Here the subscript refers to the iteration index. The summary of Algorithm 2.1 is given as follows.

```
Algorithm 2.1 Inexact Riemannian gradient decent method.
Initilization: \(X_{0}=\pi_{r}\left(P_{\Omega}(A)\right), \Omega\) is a set of cardinality \(m\) sampled uniformly at
random.
for \(l=0,1, \cdots\), do
1: \(G_{l}=P_{\Omega}\left(A-X_{l}\right)\);
2: \(\alpha_{l}=\frac{\left\langle P_{T_{l}}\left(G_{l}\right), P_{T_{l}}\left(G_{l}\right)\right\rangle}{\left\langle P_{T_{l}}\left(G_{l}\right), P_{\Omega} P_{T_{l}}\left(G_{l}\right)\right\rangle} ;\)
3: \(W_{l}=X_{l}+\alpha_{l} P_{T_{l}}\left(G_{l}\right)\);
4: \(W_{l}^{\prime}=\pi_{+}\left(W_{l}\right)\);
5: \(X_{l+1}=\pi_{r}\left(W_{l}^{\prime}\right)\);
end for
Output: \(X_{l}\) when the stopping criterion is satisfied.
```

We see from Step 4 that we projects the iterate $W_{l}$ (which is derived by updating from $X_{l}$ along the gradient descent direction on $T_{l}$ ) onto the nonnegative matrix manifold $\mathcal{M}_{n}$ to get $W_{l}^{\prime}$ via $\pi_{2}$. In Step $5, X_{l+1}$ is updated by using the svd truncation of $W_{l}^{\prime}$.

In order to show the new sequence generated by Algorithm 2.1 is convergent, the following lemma proposed in [17] will be used in the sequel.

Lemma 2.1 (Lemma 4 in [17]). Let $X_{l}$ be a rank $r$ matrix and $T_{l}$ be the tangent space of the rank $r$ matrix manifold at $X_{l}$. Suppose that $X$ is another rank $r$ matrix on the manifold $\mathcal{M}_{r}$, and $\sigma_{\min }(X)$ denotes the minimum singular value of $X$. Then
(i) $\left\|\left(I-P_{T_{l}}\right) X\right\|_{F} \leq \frac{\left\|X_{l}-X\right\|_{F}^{2}}{\sigma_{\min }(X)}$,
(ii) $\left\|P_{T_{l}}-P_{T}\right\| \leq \frac{2\left\|X_{l}-X\right\|_{F}}{\sigma_{\min }(X)}$.

Next we need to prove the following results about the error in the projections.
Lemma 2.2. Let $X$ and $X_{l}$ be two rank $r$ matrices. Denote $p$ as the sampling rate and suppose $T$ and $T_{l}$ are the tangent spaces of the fixed rank $r$ matrix manifold at $X$ and $X_{l}$, respectively. Assume

$$
\begin{equation*}
\left\|P_{T}-p^{-1} P_{T} P_{\Omega} P_{T}\right\| \leq \varepsilon_{0} \tag{2.7}
\end{equation*}
$$

and

$$
\begin{equation*}
\frac{\left\|X_{l}-X\right\|_{F}}{\sigma_{\min }(X)} \leq \frac{\varepsilon_{0} p^{\frac{1}{2}}}{4\left(1+\varepsilon_{0}\right)} \tag{2.8}
\end{equation*}
$$

are satisfied for some $0<\varepsilon_{0}<1$. Then

$$
\begin{equation*}
\left\|P_{\Omega} P_{T_{l}}\right\| \leq\left(1+\varepsilon_{0}\right) p^{\frac{1}{2}} \quad \text { and } \quad\left\|P_{T_{l}}-p^{-1} P_{T_{l}} P_{\Omega} P_{T_{l}}\right\| \leq \frac{5 \varepsilon_{0}}{2} \tag{2.9}
\end{equation*}
$$

Proof. For the first inequality in (2.9). It follows from (2.7) that

$$
\left\|P_{T} P_{\Omega} P_{T}\right\| \leq\left(1+\varepsilon_{0}\right) p
$$

Then for any matrix $Z \in \mathbb{R}^{n_{1} \times n_{2}}$, we have

$$
\begin{aligned}
\left\|P_{\Omega} P_{T}(Z)\right\|_{F}^{2} & =\left\langle P_{\Omega} P_{T}(Z), P_{\Omega} P_{T}(Z)\right\rangle \\
& =\left\langle P_{T}(Z), P_{T} P_{\Omega} P_{T}(Z)\right\rangle \\
& \leq\left(1+\varepsilon_{0}\right) p\left\|P_{T}(Z)\right\|_{F}^{2}
\end{aligned}
$$

Thus $\left\|P_{\Omega} P_{T}\right\| \leq \sqrt{\left(1+\varepsilon_{0}\right) p}$. Moreover,

$$
\begin{aligned}
\left\|P_{\Omega} P_{T_{l}}\right\| & \leq\left\|P_{\Omega}\left(P_{T_{l}}-P_{T}\right)\right\|+\left\|P_{\Omega} P_{T}\right\| \leq \frac{2\left\|X_{l}-X\right\|_{F}}{\sigma_{\min }(X)}+\left\|P_{\Omega} P_{T}\right\| \\
& \leq \frac{\varepsilon_{0} p^{\frac{1}{2}}}{2\left(1+\varepsilon_{0}\right)}+\sqrt{\left(1+\varepsilon_{0}\right) p} \leq\left(1+\varepsilon_{0}\right) p^{\frac{1}{2}}
\end{aligned}
$$

The second inequality can proved by (ii) of Lemma 2.1. Setting $t=\sqrt{\left(1+\varepsilon_{0}\right)}>1$, then $2 t^{4}-2 t^{3}-t^{2}+1=\left(t^{2}-1\right)\left(2 t^{2}-t-1\right)>0$ is satisfied and the last inequality can be derived.

For the second inequality in (2.9). With the above tools in hand we have

$$
\begin{aligned}
&\left\|P_{T_{l}}-p^{-1} P_{T_{l}} P_{\Omega} P_{T_{l}}\right\| \leq \| \\
& \quad P_{T_{l}}-P_{T}\left\|+p^{-1}\right\| P_{T} P_{\Omega} P_{T}-P_{T_{l}} P_{\Omega} P_{T} \| \\
& \quad+p^{-1}\left\|P_{T_{l}} P_{\Omega} P_{T_{l}}-P_{T_{l}} P_{\Omega} P_{T}\right\|+\left\|P_{T}-p^{-1} P_{T} P_{\Omega} P_{T}\right\| \\
& \leq\left\|P_{T_{l}}-P_{T}\right\|+p^{-1}\left\|P_{T}-P_{T_{l}}\right\|\left\|P_{\Omega} P_{T}\right\| \\
& \quad+p^{-1}\left\|P_{T_{l}} P_{\Omega}\right\|\left\|P_{T_{l}}-P_{T}\right\|+\left\|P_{T}-p^{-1} P_{T} P_{\Omega} P_{T}\right\| \\
& \leq \frac{2 \varepsilon_{0} p^{\frac{1}{2}}}{4\left(1+\varepsilon_{0}\right)}+\frac{2 \varepsilon_{0}}{4 \sqrt{\left(1+\varepsilon_{0}\right)}}+\frac{\varepsilon_{0}}{2}+\varepsilon_{0} \leq \frac{5 \varepsilon_{0}}{2} .
\end{aligned}
$$

The proof is completed.
Lemma 2.3 (Lemma 4.6 in [17]). Assume the second inequality given in (2.9) is satisfied. Then the stepsize $\alpha_{l}$ in Algorithm 2.1 can be bounded as

$$
\frac{2}{\left(2+5 \varepsilon_{0}\right) p} \leq \alpha_{l}=\frac{\left\|P_{T_{l}}\left(G_{l}\right)\right\|_{F}^{2}}{\left\langle P_{T_{l}}\left(G_{l}\right), P_{\Omega} P_{T_{l}}\left(G_{l}\right)\right\rangle} \leq \frac{2}{\left(2-5 \varepsilon_{0}\right) p} .
$$

Then we can prove the following theorem about errors of the iterates.
Theorem 2.1. Suppose the inequality given in (2.7) and

$$
\begin{equation*}
\frac{\left\|X_{0}-A\right\|_{F}}{\sigma_{\min }(A)} \leq \frac{\varepsilon_{0} p^{\frac{1}{2}}}{4\left(1+\varepsilon_{0}\right)} \tag{2.10}
\end{equation*}
$$

are satisfied with $\varepsilon_{0}$ being a positive numerical constant such that $\beta_{1}=\frac{22 \varepsilon_{0}}{2-5 \varepsilon_{0}}<1$. Then the iterates $X_{l}$ generated by Algorithm 2.1 satisfy

$$
\begin{equation*}
\left\|X_{l}-A\right\|_{F} \leq \beta_{1}^{l}\left\|X_{0}-A\right\|_{F}, \quad l=1,2, \cdots \tag{2.11}
\end{equation*}
$$

Proof. We can prove (2.11) by induction. Suppose that in the $l$-th interaction $X_{l}$ satisfies

$$
\begin{equation*}
\frac{\left\|X_{l}-A\right\|_{F}}{\sigma_{\min }(A)} \leq \frac{p^{\frac{1}{2}} \varepsilon_{0}}{4\left(1+\varepsilon_{0}\right)} \tag{2.12}
\end{equation*}
$$

with $\sigma_{\min }(A)$ is the minimum nonzero singular of $A$. Recall that (2.7) is satisfied, then by Lemma 2.2, we have

$$
\begin{align*}
& \left\|P_{\Omega} P_{T_{l}}\right\| \leq\left(1+\varepsilon_{0}\right) p^{\frac{1}{2}}  \tag{2.13a}\\
& \left\|P_{T_{l}}-p^{-1} P_{T_{l}} P_{\Omega} P_{T_{l}}\right\| \leq \frac{5 \varepsilon_{0}}{2} \tag{2.13b}
\end{align*}
$$

For the third step in Algorithm 2.1, denote $W_{l+1}=\pi_{+}\left(X_{1}+\alpha_{l} P_{T_{l}}\left(G_{l}\right)\right)$, we have

$$
\begin{align*}
\left\|X_{l+1}-A\right\|_{F} & =\left\|X_{l+1}-W_{l}+W_{l+1}-A\right\|_{F} \\
& \leq\left\|X_{l+1}-W_{l+1}\right\|_{F}+\left\|W_{l+1}-A\right\|_{F} \\
& \leq 2\left\|W_{l+1}-A\right\|_{F} \tag{2.14}
\end{align*}
$$

The second inequality is derived by noting that $X_{l+1}$ is the optimal rank $r$ approximation of $W_{l+1}$. Noting that the underling matrix $A$ is nonnegative, then after adding a nonnegative projection $\pi_{+}$in the proposed Algorithm 2.1, the iterative result of each step will be closer to the underling matrix, i.e.,

$$
\begin{equation*}
\left\|W_{l+1}-A\right\|_{F}=\left\|\pi_{+}\left(W_{l}\right)-A\right\|_{F} \leq\left\|W_{l}-A\right\|_{F} . \tag{2.15}
\end{equation*}
$$

The projection $\pi_{+}$can help us to improve the effectiveness of the proposed algorithms which can be seen from the experiments results given in Section 4. Combing (2.14) and (2.15) and plugging $W_{l}=X_{1}+\alpha_{l} P_{T_{l}}\left(G_{l}\right)$ gives

$$
\begin{align*}
&\left\|X_{l+1}-A\right\|_{F} \leq 2\left\|X_{l}+\alpha_{l} P_{T_{l}}\left(G_{l}\right)-A\right\|_{F} \\
&= 2\left\|X_{l}-A-\alpha_{l} P_{T_{l}} P_{\Omega}\left(X_{l}-A\right)\right\|_{F} \\
& \leq 2\left\|\left(P_{T_{l}}-\alpha_{l} P_{T_{l}} P_{\Omega} P_{T_{l}}\right)\left(X_{l}-A\right)\right\|_{F}+2\left\|\left(I-P_{T_{l}}\right)\left(X_{l}-A\right)\right\|_{F} \\
& \quad+2 \mid \alpha_{l}\left\|P_{T_{l}} P_{\Omega}\left(I-P_{T_{l}}\right)\left(X_{l}-A\right)\right\|_{F} \\
&= I_{1}+I_{2}+I_{3} . \tag{2.16}
\end{align*}
$$

For $I_{1}$, applying Lemma 2.2 gives

$$
I_{1}=2\left\|\left(P_{T_{l}}-\alpha_{l} P_{T_{l}} P_{\Omega} P_{T_{l}}\right)\left(X_{l}-A\right)\right\|_{F} \leq \frac{20 \varepsilon_{0}}{2-5 \varepsilon_{0}}\left\|X_{l}-A\right\|_{F}
$$

For $I_{2}$, by (i) of Lemma 2.1 and the assumption given in (2.12), we have

$$
\begin{aligned}
I_{2} & =2\left\|\left(I-P_{T_{l}}\right)(A)\right\|_{F} \leq \frac{2\left\|X_{l}-A\right\|_{F}^{2}}{\sigma_{\min }(X)} \\
& \leq \frac{p^{1 / 2} \varepsilon_{0}}{2\left(1+\varepsilon_{0}\right)}\left\|X_{l}-A\right\|_{F} \leq \frac{\varepsilon_{0}}{2-5 \varepsilon_{0}}\left\|X_{l}-A\right\|_{F} .
\end{aligned}
$$

For $I_{3}$, by the bound of $\alpha_{l}$ given in Lemma 2.3, the bound of the spectral norm of $P_{\Omega} P_{T_{l}}$ given in Lemma 2.2 and the assumption given in (2.12), we have

$$
\begin{aligned}
I_{3} & \leq 2\left|\alpha_{l}\right|\left\|P_{\Omega} P_{T_{l}}\right\|\left\|\left(I-P_{T_{l}}\right)(A)\right\|_{F} \\
& \leq \frac{4}{\left(2-5 \varepsilon_{0}\right)}\left(1+\varepsilon_{0}\right) p^{1 / 2} \frac{\left\|X_{l}-A\right\|_{F}^{2}}{\sigma_{\min }(A)} \\
& \leq \frac{\varepsilon_{0}}{2-5 \varepsilon_{0}}\left\|X_{l}-A\right\|_{F} .
\end{aligned}
$$

Taking the bounds of $I_{1}, I_{2}$ and $I_{3}$ into (2.16) gives

$$
\left\|X_{l+1}-A\right\|_{F} \leq \beta_{1}\left\|X_{l}-A\right\|_{F},
$$

where $\beta_{1}=\frac{22 \varepsilon_{0}}{2-5 \varepsilon_{0}}<1$. Note that (2.16) is satisfied for $l=0$ by the assumption of Theorem 2.1, then the sequence derived by Algorithm 2.1 is contractive.

In Algorithm 2.1, a SVD truncation is needed to project $W_{l+1}$ back to the manifold $\mathcal{M}_{r}$. Such computational procedure can be expensive. Here we further modify the step by using the tangent space of the iterate to find an approximation of the $\pi_{r}\left(W_{l+1}\right)$ on the manifold such that the computational cost can be reduced. The idea is shown as in Fig. 1 for illustration. Similar to the results in [17], the overall computational cost of $\pi_{r}\left(P_{T_{l}}\left(W_{l}^{\prime}\right)\right)$ in Algorithm 2.2 can be expressed as two matrix-matrix multiplications. In addition, the calculation procedure involves the QR decomposition of two matrices of sizes $n_{1} \times r$ and $n_{2} \times r$ matrices, and the SVD of a matrix of size $2 r \times 2 r$. The total cost per iteration is of $4 n_{1} n_{2} r+O\left(n_{1} r^{2}+n_{2} r^{2}+r^{3}\right)$. In contrast, the computation of the best rank- $r$ approximation of a non-structured $n_{1} \times n_{2}$ matrix costs $\mathcal{O}\left(n_{1} n_{2} r\right)+n_{1} n_{2}$ flops where the constant in front of $n_{1} n_{2} r$ can be very large. In practice, the cost per iteration of the proposed Inexact Riemannian gradient decent method using tangent spaces (InRGD-TS) is less than that of original Inexact Riemannian gradient decent method (InRGD). In Section 4, numerical examples are given to demonstrate the total computational time of the proposed InRGD-TS method is less than that of the InRGD method. The resulting algorithm is listed in Algorithm 2.2. Here $\mathcal{M}_{r}, X_{0}, T_{l}$ and $P_{T_{l}}$ are defined as in Algorithm 2.1. $\mathcal{M}_{n}$ denotes the nonnegative matrices manifold. For Algorithm 2.2, we can show its convergence stated in Theorem 2.2.

```
Algorithm 2.2 Inexact Riemannian gradient decent method using tangent spaces.
Initilization: \(X_{0}=\pi_{r}\left(P_{\Omega}(A)\right), \Omega\) is a set of cardinality \(m\) sampled uniformly at
random.
for \(l=0,1, \cdots\), do
1: \(G_{l}=P_{\Omega}\left(A-X_{0}\right)\);
2: \(\alpha_{l}=\frac{\left\langle P_{T_{l}}\left(G_{l}\right), P_{T_{l}}\left(G_{l}\right)\right\rangle}{\left\langle P_{T_{l}}\left(G_{l}\right), P_{\Omega} P_{T_{l}}\left(G_{l}\right)\right\rangle}\);
3: \(W_{l}=X_{l}+\alpha_{l} P_{T_{l}}\left(G_{l}\right)\);
4: \(W_{l}^{\prime}=\pi_{+}\left(W_{l}\right)\);
5: \(Y_{l}=P_{T_{l}}\left(W_{l}^{\prime}\right)\);
6: \(X_{l+1}=\pi_{r}\left(Y_{l}\right)\);
end for
Output: \(X_{l}\) when the stopping criterion is satisfied.
```

Theorem 2.2. Let $\mathcal{M}_{r}, A$ and $T$ be given as in Theorem 2.1. Assume (2.7) and (2.10) are satisfied with $\varepsilon_{0}$ being a positive numerical constant such that $\beta_{2}=\frac{132 \varepsilon_{0}}{2-5 \varepsilon_{0}}<1$. Then the iterates $X_{l}$ generated by Algorithm 2.2 satisfy

$$
\begin{equation*}
\left\|X_{l}-A\right\|_{F} \leq \beta_{2}^{l}\left\|X_{0}-A\right\|_{F}, \quad l=1,2, \cdots \tag{2.17}
\end{equation*}
$$

Proof. Similar to the proof of Theorem 2.1, we can prove (2.17) by induction. Suppose in the $l$-th interation $X_{l}$ in Algorithm 2.2 satisfies (2.12). Then (2.13a) and (2.13b) can be derived. Denote $W_{l}=X_{l}+\alpha_{l} P_{T_{l}}\left(G_{l}\right)$, and $Y_{l}=P_{T_{l}}\left(\pi_{+}\left(W_{l}\right)\right)$. Note that $X_{l+1}$ is the optimal rank $r$ approximation of $Y_{l}$, and $Y_{l}$ is the closest point of $\pi_{+}\left(W_{l}\right)$ on the tangent space $T_{l}$, we have

$$
\begin{aligned}
\left\|X_{l+1}-X\right\|_{F} & =\left\|X_{l+1}-Y_{l}+Y_{l}-A\right\|_{F} \\
& \leq\left\|X_{l+1}-Y_{l}\right\|_{F}+\left\|Y_{l}-A\right\|_{F} \leq 2\left\|Y_{l}-A\right\|_{F} \\
& =2\left\|P_{T_{l}}\left(\pi_{+}\left(W_{l}\right)\right)-\pi_{+}\left(W_{l}\right)+\pi_{+}\left(W_{l}\right)-A\right\|_{F} \\
& \leq 2\left\|P_{T_{l}}\left(\pi_{+}\left(W_{l}\right)\right)-\pi_{+}\left(W_{l}\right)\right\|_{F}+2\left\|\pi_{+}\left(W_{l}\right)-A\right\|_{F} \\
& \leq 2\left\|\pi_{+}\left(W_{l}\right)-W_{l}\right\|_{F}+2\left\|\pi_{+}\left(W_{l}\right)-A\right\|_{F} \\
& =2\left\|\pi_{+}\left(W_{l}\right)-A+A-X_{l}-\alpha_{l} P_{T_{l}}\left(G_{l}\right)\right\|_{F}+2\left\|\pi_{+}\left(W_{l}\right)-A\right\|_{F} \\
& \leq 2\left\|\pi_{+}\left(W_{l}\right)-A\right\|_{F}+2\left\|X_{l}+\alpha_{l} P_{T_{l}}\left(G_{l}\right)-A\right\|_{F}+2\left\|\pi_{+}\left(W_{l}\right)-A\right\|_{F} \\
& \leq 6\left\|X_{l}+\alpha_{l} P_{T_{l}}\left(G_{l}\right)-A\right\|_{F} .
\end{aligned}
$$

Analogous to (2.15),

$$
\left\|\pi_{+}\left(W_{l}\right)-A\right\|_{F} \leq\left\|W_{l}-A\right\|_{F}=\left\|X_{l}+\alpha_{l} P_{T_{l}}\left(G_{l}\right)-A\right\|_{F}
$$

can be derived and the last inequality follows. After choosing some suitable $\varepsilon_{0}$ such that $\beta_{2}=\frac{132 \varepsilon_{0}}{2-5 \varepsilon_{0}}<1$, and by the proof of Theorem 2.1 we have (2.17) is satisfied for $l+1$. Then, by the assumption of Theorem 2.2, (2.17) is satisfied when $l=0$. Combine them together, the iterates $X_{l}$ generated by Algorithm 2.2 is convergent.

Remark 2.1. Besides Inexact Riemannian gradient descent methods, we can employ Inexact Riemannian conjugate gradient methods to solve the nonnegative matrix completion problem. In the Inexact Riemannian conjugate gradient method, the search direction is a linear combination of the projected gradient descent direction and the past search direction projected onto the tangent space of the current iterate. Similar to Theorems 2.1 and 2.2, the underlying nonnegative matrix can be exactly recovered by the Inexact Riemannian conjugate gradient method.

## 3 The initialization and sampling complexity

In this section, we mainly study the number of observed entries required to exactly recover the underling nonnegative low rank matrix. In this case, we need to introduce the following definitions firstly.

Definition 3.1 (Definition 1.2 in [1]). Let $X \in \mathbb{R}^{n_{1} \times n_{2}}$ be a rank $r$ matrix with the skinny singular value decomposition (SVD) as $X=U S V^{T}$. We assume $X$ is $\mu_{0}$ incoherent, that is, there exists an absolute numerical constant $\mu_{0}>0$ such that

$$
\left\|P_{U}\left(e_{i}\right)\right\| \leq \sqrt{\frac{\mu_{0} r}{n_{1}}} \quad \text { and } \quad\left\|P_{V}\left(e_{j}\right)\right\| \leq \sqrt{\frac{\mu_{0} r}{n_{2}}}
$$

for $1 \leq i \leq n_{1}, 1 \leq j \leq n_{2}$. Here $e_{l}(l=i, j)$ is the $l$-th canonical basis of $\mathbb{R}^{n_{1}}$ and $\mathbb{R}^{n_{2}}$, $P_{U}$ and $P_{V}$ are the orthogonal projections onto the column and row spaces of $X$, respectively.

The two conditions given in (2.7) and (2.10) in Theorem 2.1 are used to guarantee the convergence of Algorithm 2.1. For (2.7), it is a local restricted isometry property which is saying that the operator $P_{T} P_{\Omega} P_{T}$ is close to an isometry on $T$ if the number of the observed entries is big enough. Under the framework of Bernoulli sampling model, Candes and Retha [1] demonstrated that (2.7) plays a key role in nuclear norm minimization for matrix completion problem. In the following discussion, we set $s=\max \left\{n_{1}, n_{2}\right\}, t=\min \left\{n_{1}, n_{2}\right\}$.

Lemma 3.1 (Theorem 4.1 in [1]). Let $X \in \mathbb{R}^{n_{1} \times n_{2}}$ be a $\mu_{0}$-incoherent matrix with rank $r$. Suppose $\Omega$ with $|\Omega|=m$ is sampled according to the Bernoulli model. Then for all $\beta>1$

$$
\left\|\frac{n_{1} n_{2}}{m} P_{T} P_{\Omega} P_{T}-P_{T}\right\|_{o p} \lesssim \sqrt{\frac{\mu_{0} r s \beta \log s}{m}}
$$

holds with probability at least $1-3 s^{-\beta}$ provided that $m \gtrsim \mu_{0} r \beta s \log s$.
It follows from Lemma 3.1 that (2.7) is satisfied with probability at least $1-3 s^{-\beta}$, as long as $m \gtrsim \mu_{0} r \beta s \log s$, where $\mu_{0}$ is the incoherence condition constant stated in Definition 3.1.

For (2.10), it is required to determine an initial guess that falls within a certain small area of the underlying nonnegative matrix. If it is valid, the sequence generated by Algorithm 2.1 can guarantee to converge linearly to the underling nonnegaive low rank matrix. Here we adapt the trimming scheme proposed in $[6,17]$ to construct an initial guess. More precisely, the scheme is implemented by dividing the sampling set $\Omega$ into $L+1$ parts, such that $\Omega=\bigcup_{i=0}^{L} \Omega_{i}$ and the initialization matrix was constructed
by values from the $L+1$ subsets of $\Omega$ independently. In our setting, there is a nonnegative projection as given in (2.4) to make sure the elements of the trimming results are nonnegative. The scheme is given in Algorithm 3.1.

```
Algorithm 3.1 Initialization via resampled method and trimming method.
Partition \(\Omega\) into \(L+1\) equal groups, i.e., \(\Omega=\bigcup_{i=0}^{L} \Omega_{i},\left|\Omega_{0}\right|=\cdots=\left|\Omega_{L}\right|=\frac{m}{L+1}=\hat{m}\).
Set \(Z_{0}=\pi_{r}\left(\frac{n_{1} n_{2}}{\hat{m}} P_{\Omega_{0}}(A)\right)\)
for \(l=0, \cdots, L-1\) do
\(1: Z_{l}=U_{l} \Sigma_{r} V_{l}^{T}\);
2: \(\hat{Z}_{l}=A_{l}^{(i)} \Sigma_{r}\left(B_{l}^{(i)}\right)^{T}\), where
```

$$
A_{l}^{(i)}=\frac{U_{l}^{(i)}}{\left\|U_{l}^{(i)}\right\|} \min \left\{\left\|U_{l}^{(i)}\right\|, \sqrt{\frac{\mu_{0} r}{n_{1}}}\right\}, \quad B_{l}^{(i)}=\frac{V_{l}^{(i)}}{\left\|V_{l}^{(i)}\right\|} \min \left\{\left\|V_{l}^{(i)}\right\|, \sqrt{\frac{\mu_{0} r}{n_{2}}}\right\}
$$

3: $Z_{l+1}^{\prime}=\pi_{r}\left(\hat{Z}_{l}+\frac{n_{1} n_{2}}{\tilde{m}} P_{\hat{T}_{l}} P_{\Omega_{l+1}}\left(X-\hat{Z}_{l}\right)\right)$;
4: $Z_{l+1}=\pi_{+}\left(Z_{l+1}^{\prime}\right)$;
end for
Output: $X_{0}=Z_{L}$
Next we show the output of Algorithm 3.1 falls within the neighborhood required by (2.10). Let us first state the following lemma.

Lemma 3.2 (Theorem 6.3 in [1]). Suppose $X \in \mathbb{R}^{n_{1} \times n_{2}}$, and $\Omega$ with $|\Omega|=m$ is a set of indices sampled according to the Bernoulli model. Then for all $\beta>2$

$$
\left\|\left(I-\frac{n_{1} n_{2}}{m} P_{\Omega}\right) X\right\| \lesssim \sqrt{\frac{s^{2} t \beta \log s}{m}}\|X\|_{\infty}
$$

holds with probability at least $1-s^{-\beta}$ provided $m \gtrsim \beta s \log s$.
By Lemma 3.2 and the incoherence conditions listed in Definition 3.1, the distance between the initiation value $Z_{0}$ in Algorithm 3.1 and the underlying matrix $X$ can be estimated as follows.

Lemma 3.3. Suppose $X \in \mathbb{R}^{n_{1} \times n_{2}}$ satisfies the incoherence conditions given in Definition $3.1, \Omega$ with $|\Omega|=m$ is a set of indices sampled according to the Bernoulli model. Let $\Omega_{i}, i=0, \cdots, L$ be a division of $\Omega$ given in Algorithm 3.1 and $Z_{0}=\pi_{r}\left(\frac{n_{1} n_{2}}{\tilde{m}} P_{\Omega_{0}}(X)\right)$. Then for all $\beta>2$,

$$
\begin{equation*}
\left\|Z_{0}-X\right\|_{F} \leq \frac{\sigma_{\min }(X)}{256 \kappa^{2}} \tag{3.1}
\end{equation*}
$$

holds with probability at least $1-s^{-\beta}$ provided that

$$
\hat{m} \gtrsim \mu_{0}^{2} \beta \kappa^{6} r^{2} s \log s
$$

Proof. Set $W_{0}=\frac{n_{1} n_{2}}{\hat{m}} P_{\Omega_{0}}(X)$. First,

$$
\left\|Z_{0}-X\right\| \leq\left\|Z_{0}-W_{0}\right\|+\left\|W_{0}-X\right\| \leq 2\left\|W_{0}-X\right\| \leq 2 \sqrt{\frac{s^{2} t \beta \log s}{\hat{m}}}\|X\|_{\infty}
$$

where the third inequality can be derived by Lemma 3.2 which holds with probability at least $1-s^{-\beta}$. And then

$$
\begin{aligned}
\left\|Z_{0}-X\right\|_{F} & \leq \sqrt{2 r}\left\|Z_{0}-X\right\| \leq \sqrt{\frac{8 s^{2} t r \log s}{\hat{m}}}\|X\|_{\infty} \\
& \leq \sqrt{\frac{8 \mu_{0}^{2} s r^{2} \log s}{\hat{m}}}\|X\| \leq \frac{\sigma_{\min }(X)}{256 \kappa^{2}}
\end{aligned}
$$

The third inequality is followed from the fact that

$$
\|X\|_{\infty}=\left\|U \Sigma V^{T}\right\|_{\infty} \leq \frac{\mu_{0} r}{t} \sigma_{\max }
$$

the fourth inequality is derived by $\hat{m} \gtrsim \mu_{0}^{2} \beta \kappa^{6} r^{2} s \log s$.
Lemma 3.4. Suppose $X \in \mathbb{R}^{n_{1} \times n_{2}}$ with $\operatorname{rank}(X)=r, \kappa$ is the condition number of $X$ and $L$ is defined as in Algorithm 3.1. Then for all $\beta>1$, the output of Algorithm 3.1 satisfies

$$
\left\|X_{0}-X\right\|_{F} \leq\left(\frac{5}{6}\right)^{L} \frac{\sigma_{\min }(X)}{256 \kappa^{2}}
$$

with high probability provided

$$
\hat{m} \gtrsim \mu_{0}^{2} r^{2} \kappa^{6} s \beta \log s .
$$

Proof. For $l=0, Z_{0}=\pi_{r}\left(\frac{n_{1} n_{2}}{\hat{m}} P_{\Omega_{0}}(X)\right)$, then by Lemma 3.3 we have

$$
\left\|Z_{0}-X\right\|_{F} \leq \frac{\sigma_{\min }(X)}{256 \kappa^{2}}
$$

satisfied with high probability provided

$$
\begin{equation*}
\hat{m} \gtrsim \mu_{0}^{2} \beta \kappa^{6} r^{2} s \log s . \tag{3.2}
\end{equation*}
$$

Assume that

$$
\begin{equation*}
\left\|Z_{l}-X\right\|_{F} \leq\left(\frac{5}{6}\right)^{l} \frac{\sigma_{\min }(X)}{256 \kappa^{2}} \tag{3.3}
\end{equation*}
$$

Then by Lemma 13 in [17], we have $\hat{Z}_{l}$ is an incoherent matrix with incoherence parameter $\frac{100}{81} \mu_{0}$ and

$$
\left\|\hat{Z}_{l}-X\right\|_{F} \leq 8 \kappa\left\|Z_{l}-X\right\|_{F}
$$

Denote

$$
W_{l}=\hat{Z}_{l}+\frac{n_{1} n_{2}}{\hat{m}} P_{\hat{T}_{l}} P_{\Omega_{l+1}}\left(X-\hat{Z}_{l}\right) \quad \text { and } \quad Z_{l+1}^{\prime}=\pi_{1}\left(W_{l}\right)
$$

Note that $X$ is nonnegative and $Z_{l+1}^{\prime}$ is the optimal rank $r$ approximation of $W_{l}$, then the approximation error at the $(l+1)$ th iteration can be decomposed as

$$
\begin{aligned}
\left\|Z_{l+1}-X\right\|_{F}= & \left\|\pi_{+}\left(Z_{l+1}^{\prime}\right)-X\right\|_{F} \leq\left\|Z_{l+1}^{\prime}-X\right\|_{F} \\
= & \left\|Z_{l+1}^{\prime}-W_{l}+W_{l}-X\right\|_{F} \\
\leq & 2\left\|\hat{Z}_{l}+\frac{n_{1} n_{2}}{\hat{m}} P_{\hat{T}_{l}} P_{\Omega_{l+1}}\left(X-\hat{Z}_{l}\right)-X\right\|_{F} \\
\leq & 2\left\|\left(P_{\hat{T}_{l}}-\frac{n_{1} n_{2}}{\hat{m}} P_{\hat{T}_{l}} P_{\Omega_{l+1}} P_{\hat{T}_{l}}\right)\left(\hat{Z}_{l}-X\right)\right\|_{F}+2\left\|\left(I-P_{\hat{T}_{l}}\right)\left(\hat{Z}_{l}-X\right)\right\|_{F} \\
& +2\left\|\frac{n_{1} n_{2}}{\hat{m}} P_{\hat{T}_{l}} P_{\Omega_{l+1}}\left(I-P_{\hat{T}_{l}}\right)\left(\hat{Z}_{l}-X\right)\right\|_{F} \\
:= & I_{5}+I_{6}+I_{7} .
\end{aligned}
$$

Applying Lemma 3.1 to

$$
\left\|P_{\hat{T}_{l}}-\frac{n_{1} n_{2}}{\hat{m}} P_{\hat{T}_{l}} P_{\Omega_{l+1}} P_{\hat{T}_{l}}\right\|
$$

in $I_{5}$ gives

$$
I_{5} \leq \kappa \sqrt{\frac{100 \mu_{0} \beta r s \log s}{81 \hat{m}}}\left\|Z_{l}-X\right\|_{F}
$$

holds with high probability.
By applying (i) of Lemma 2.1 and recall the assumption (3.3), we have

$$
I_{6} \leq \frac{2\left\|\hat{Z}_{l}-X\right\|_{F}^{2}}{\sigma_{\min }(X)} \leq \frac{128 \kappa^{2}\left\|Z_{l}-X\right\|_{F}^{2}}{\sigma_{\min }(X)} \leq \frac{1}{2}\left\|Z_{l}-X\right\|_{F}
$$

Note that $\hat{Z}_{l}$ is independent of $\Omega_{l+1}$ with the incoherence parameter $\frac{100}{81} \mu_{0}$, then it follows from Lemma 6 in [17] that

$$
\left\|\frac{n_{1} n_{2}}{\hat{m}} P_{T_{l}} P_{\Omega_{l+1}}\left(P_{U}-P_{U_{l}}\right)-P_{T_{l}}\left(P_{U}-P_{U_{l}}\right)\right\| \leq \sqrt{\frac{4800 \mu_{0} s \beta r \log s}{81 \hat{m}}}
$$

holds with high probability. Moreover, due to $X=U U^{T} X$ and $P_{\hat{T}_{l}}\left(\hat{Z}_{l}\right)=\hat{Z}_{l}$, we have

$$
\begin{aligned}
\left(I-P_{\hat{T}_{l}}\right)\left(\hat{Z}_{l}-X\right) & =-\left(I-P_{\hat{T}_{l}}\right)(X) \\
& =-U U^{T} X+\hat{U}_{l} \hat{U}_{l}^{T} X+U U^{T} X \hat{V}_{l} \hat{V}_{l}^{T}-\hat{U}_{l} \hat{U}_{l}^{T} X \hat{V}_{l} \hat{V}_{l}^{T} \\
& =-\left(U U^{T}-\hat{U}_{l} \hat{U}_{l}^{T}\right) X\left(I-\hat{V}_{l} \hat{V}_{l}^{T}\right) \\
& =\left(P_{U}-P_{\hat{U}_{l}}\right)\left(\hat{Z}_{l}-X\right)\left(I-P_{\hat{V}_{l}}\right) .
\end{aligned}
$$

Together with

$$
P_{\hat{T}_{l}}\left(\left(P_{U}-P_{\hat{U}_{l}}\right)\left(\hat{Z}_{l}-X\right)\left(I-P_{\hat{V}_{l}}\right)\right)=P_{\hat{T}_{l}}\left(\left(I-P_{\hat{T}_{l}}\right)\left(\hat{Z}_{l}-X\right)\right)=0
$$

$I_{7}$ can be bounded as follows,

$$
\begin{aligned}
I_{7} & =2\left\|\frac{n_{1} n_{2}}{\hat{m}} P_{\hat{T}_{l}} P_{\Omega_{l+1}}\left(I-P_{\hat{T}_{l}}\right)\left(\hat{Z}_{l}-X\right)\right\|_{F} \\
& =2\left\|\frac{n_{1} n_{2}}{\hat{m}} P_{\hat{T}_{l}} P_{\Omega_{l+1}}\left(I-P_{\hat{T}_{l}}\right)\left(\hat{Z}_{l}-X\right)-P_{\hat{T}_{l}}\left(I-P_{\hat{T}_{l}}\right)\left(\hat{Z}_{l}-X\right)\right\|_{F} \\
& \leq 2\left\|\frac{n_{1} n_{2}}{\hat{m}}\left(P_{\hat{T}_{l}} P_{\Omega_{l+1}}-P_{\hat{T}}\right)\left(P_{U}-P_{\hat{U}_{l}}\right)\right\|\left\|\hat{Z}_{l}-X\right\|_{F} \\
& \leq 2 \sqrt{\frac{4800 \mu_{0} \beta s r \log s}{81 \hat{m}}}\left\|\hat{Z}_{l}-X\right\|_{F} \\
& \leq 16 \kappa \sqrt{\frac{4800 \mu_{0} \beta s r \log s}{81 \hat{m}}}\left\|Z_{l}-X\right\|_{F} .
\end{aligned}
$$

Combining the bounds of $I_{5}, I_{6}$ and $I_{7}$ together, we can get

$$
\left\|Z_{l+1}-X\right\|_{F} \leq\left(\frac{1}{2}+182 \kappa \sqrt{\frac{\mu_{0} \beta s r \log s}{\hat{m}}}\right)\left\|Z_{l}-X\right\|_{F} \leq \frac{5}{6}\left\|Z_{l}-X\right\|_{F}
$$

holds with high probability provided

$$
\begin{equation*}
\hat{m} \gtrsim \mu_{0} \beta \kappa^{2} s r \log s \tag{3.4}
\end{equation*}
$$

Therefore taking a maximum of the right hand sides of (3.2) and (3.4) gives

$$
\left\|Z_{L}-X\right\|_{F} \leq\left(\frac{5}{6}\right)^{L} \frac{\sigma_{\min }(X)}{256 \kappa^{2}}
$$

with high probability provided $\hat{m} \gtrsim \mu_{0}^{2} \beta \kappa^{6} s r \log s$.
Combining the above results, we can get the following results.

Theorem 3.1. Suppose $X \in \mathbb{R}^{n_{1} \times n_{2}}$ is nonnegative with $\operatorname{rank}(X)=r, \kappa$ is the condition number of $X$. Let $\Omega(|\Omega|=m)$ be a set of indices sampled according to the Bernoulli model. Let $X_{0}$ be the output of Algorithm 3.1. Then the iterates generated by Algorithm 2.1 converge to $X$ with high probability provided

$$
m \gtrsim \frac{\mu_{0}^{2}}{\epsilon_{0}^{2}} \kappa^{6} \beta s r^{2} \log s \log \left(\frac{s \log s}{24 \epsilon_{0}}\right) .
$$

Proof. This result follows from Lemma 2.2, Theorem 2.1, and Lemma 3.4.

## 4 Experimental results

In this section, numerical results are presented to show the effectiveness of the proposed inexact Riemannian gradient descent method (InRGD) and its version using tangent spaces (InRGD-TS) for nonnegative low rank matrix competition. We also make use of our results to derive the Inexact Riemannian conjugate gradient method without using tangent spaces (InRCG) and using tangent spaces (InRCG-TS) for comparison. On the other hand, we would like to compare low rank matrix completion methods without using nonnegativity. Both Riemannian gradient descent (RGD) and Riemannian Conjugate Gradient method (RCG) (see for example [17]) are employed in the comparison. All the experiments are performed under Windows 7 and MATLAB R2018a running on a desktop (Intel Core i7, @3.40GHz, 8.00G RAM).

The relative error (RES) is defined by

$$
\mathrm{RES}=\frac{\|X-A\|_{F}}{\|A\|_{F}}
$$

where $X$ is the recovered solution and $A$ is the ground-truth nonnegative matrix. Moreover, in order to evaluate the performance for real-world nonnegative matrices, the peak signal-to-noise ratio (PSNR) is used to measure the equality of the estimated nonnegative matrices, which is defined as:

$$
\operatorname{PSNR}=10 \log _{10} \frac{n_{1} n_{2}\left(X_{\max }-X_{\min }\right)^{2}}{\|X-A\|_{F}}
$$

where $X_{\max }$ and $X_{\min }$ are maximal and minimal entries of $A$, respectively. The stopping criterion of the algorithms are all set to

$$
\frac{\left\|X_{l+1}-X_{l}\right\|_{F}}{\left\|X_{l}\right\|_{F}} \leq 10^{-5}
$$

### 4.1 Synthetic data

We perform the proposed InRGD and InRGD-TS methods, InRCG and InRCGTS methods, RGD and RCG methods on synthetic nonnegative low-rank matrix data. We randomly generate $n_{1}$-by- $r$ matrix $B$ and $r$-by- $n_{2}$ matrix $C$ with entries uniformly distributed in the interval $[0,1] . A$ is generated by normalizing $B C$ to ensure that each element belongs to $[0,1]$. Notice that we have $\operatorname{rank}\left(A_{0}\right)=r$. We set $n_{1}=500, n_{2}=800$ and $n_{1}=1000, n_{2}=800$, and choose $r=40$. We set the sampling rate $(s r)$ from 0.1 to 0.9 with step size 0.1 . Table 1 reports the average results over 10 tests of CPU Time (CPU) and the residual (RSE) $\frac{\left\|A-Y_{c}\right\|_{F}}{\|A\|_{F}}$, where $Y_{c}$ is computed matrix. According to the table, when $s r$ is in between 0.1 and 0.5 , the RSEs of the proposed methods InRGD and InRGD-TS are smaller than those of RGD and RCG. The nonnegativity constraint should be useful in the matrix recovery. Also the computational times required by InRGD and InRCG are less than that required by RGD and RCG. Because the cost of SVD decomposition is avoided, the computational times required by InRGD-TS and InRCG-TS are always less than that required by InRGD and InRCG. Moreover, the performance of InRCG and InRCG-TS is comparable with InRGD and InRGD-TS, respectively.

Table 1: Average results of 10 tests related to the Cputimes and RES of the recovered matrices by RGD, InRGD, InRGD-TS, RCG, InRCG and InRCG-TS on synthetic data.

Next we check the recovery ability of our algorithms as a function of $\operatorname{rank}(X)$ and the proportion $\rho$ of observed nonnegative entries. The data sets are generated randomly similar to Table 1. We fix the matrix size to be $n=n_{1}=n_{2}=400$, and test different values of $\rho$ and different values of $\operatorname{rank}(X) / n$. For each pair $(\operatorname{rank}(X) / n, \rho)$, we simulate ten trials and declare a trial to be successful if the recovered matrix $X$ satisfies $\frac{\|X-A\|_{F}}{\|A\|_{F}} \leq 10^{-5}$. Fig. 2 reports the recovery results of different methods (InRGD, InRCG, RGD and RCG). In the figure, a black pixel refers to failure case and a white pixel refers to a success case. It is clear from the results that

Figure 2: Recovery for varying matrix ranks and sampling numbers under the same matrix size $n=400$.

Table 2: Average results of 10 tests relate to the CPU and RES of the recovered matrices by RGD, $\operatorname{InRGD}, \operatorname{InRGD}-T S, R C G, \operatorname{InRCG}$ and $\operatorname{InRCG}-T S$ on synthetic data with Gaussian noise.

the nonnegativity projection used in InRGD and InRCG can help in the recovery underlying nonnegative low rank matrix.

Finally, we would like to show the performance of the proposed algorithm when a Gaussian noise of zero mean and variance $\sigma(=0.1,0.01,0.001)$ is added to nonnegative low rank matrices. The residuals of the computed solutions by the proposed algorithms (InRGD and InRGD-TS) are reported in Table 2. In the table, the results by the other Riemannian algorithms (InRCG and InRCG-TS) and the Riemannian algorithm without using nonnegativity projection (RGD and RCG) are also reported. Similar to Table 1, it is clear that the performance of the proposed algorithms (InRGD and InRGD-TS) is better than that of RGD and RCG when $s r$ is small.

### 4.2 Real image data

In this experiment, we present image (nonnegative pixels) completion results. The original two images "Barbara" and "Pepper" with sizes $n_{1} \times n_{2}=256 \times 256$ are shown in Fig. 3. Let $\Omega$ be the set of observed entries that are generated randomly. $\rho=$ $\frac{|\Omega|}{n_{1} \times n_{2}}$ is the percentage of observed entries. Similar to the synthetic data case, we compare our proposed InRGD and InRCG methods with the RGD and RCG matrix completion methods. Tables 3 and 4 show that the InRGD and InRCG methods perform better that the RGD and RCG methods in the RES, PSNR and SSIM values with different sampling rates, different ranks. We need to remark that if RSE is greater than 1, i.e., the algorithm failed to recover the underlying image, then "-" is used in Tables 3 and 4 to indicate these situations. The original images and some recover results under different sampling rates and ranks are given in Fig. 3.

Figure 3: Recovered images by RGD, In-RGD, RCG, In-RCG algorithms with different sampling ratios and rank choices. The original images, the observed images, the recovered images by RGD, In-RGD, RCG and In -RCG are respectively listed from the first column to the fifth column. The corresponding sampling rates, the rank assumptions, psnr and ssim values are listed at the bottom of every images.

Table 3: The RES, PSNR and SSIM values of the recovered results by RGD, InRGD, RCG and InRCG on "Barbara".

## 5 Conclusions

In this paper, Riemannian optimization methods are proposed to recover a nonnegative low rank matrix from its partial observed entries. With the underlying matrix incoherence conditions, we show that when the number $m$ of observed entries are sampled independently and uniformly without replacement, the inexact Riemannian gradient descent method can recover the underlying $n_{1}$-by- $n_{2}$ nonnegative matrix of rank $r$ provided that $m$ is of $\mathcal{O}\left(r^{2} s \log ^{2} s\right)$ with $s=\max \left\{n_{1}, n_{2}\right\}$. Numerical examples

Table 4: The RES, PSNR and SSIM values of the recovered results by RGD, InRGD, RCG and InRCG on "Pepper".

are shown that the nonnegativity property would be useful in the matrix recovery. In particular, we demonstrate the number of samples required to recover the underlying low rank matrix with using the nonnegativity property is smaller than that without using the property. As a future research work, it would be interesting to show the convergence rate of the inexact Riemannian gradient descent with i.i.d. Gaussian noise.
